Before you get started, make sure to have these account credentials ready:

- Claude
- GitHub

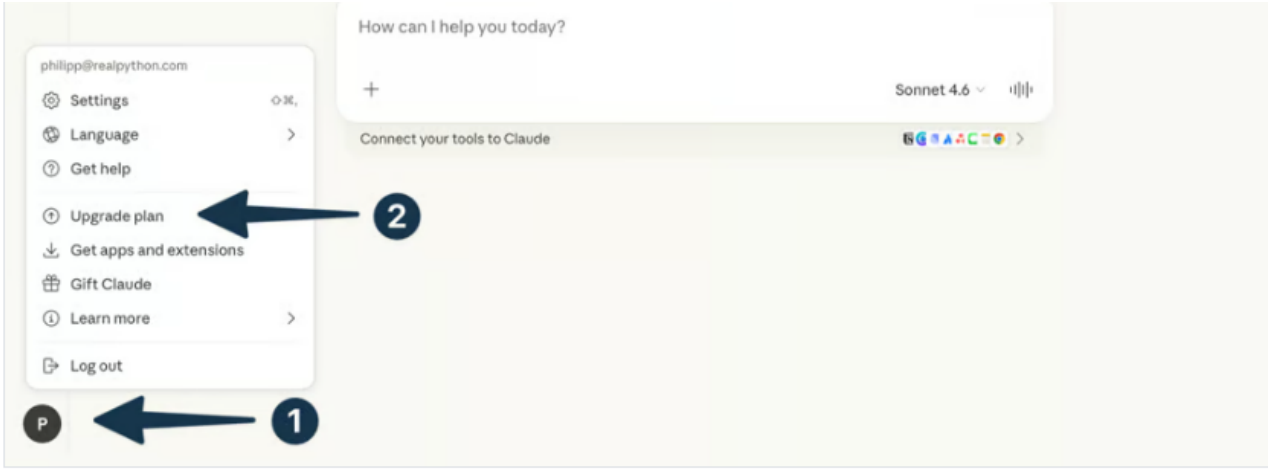

If you don't have an account, please follow the steps outlined below.

Claude

To use Claude Code you need a Claude account with a **paid** subscription plan:

1. Visit https://claude.ai/login in your browser
2. Enter your email address
3. Log in or sign up

Once you're logged in, you're seeing the regular Claude chat interface in the browser. Click your user icon on the lower left and choose *Upgrade plan*:

On the "Plans" page, choose your preferred payment interval and select one of the paid plans.

> **Our Recommendation:** While the "Pro" plan works for the live course, we highly recommend trying out the **Max Plan** for a month.

You can always upgrade your Claude plan or cancel before the next payment interval.

GitHub

During the live course you'll explore a Claude Code workflow that uses GitHub as a central hub. To follow along, you need a **free** GitHub account.

If you don't have a GitHub account yet, follow these steps:

1. Visit https://github.com/signup in your browser
2. Enter your email address and credentials
3. Click *Create account*

Please save your Claude and GitHub credentials in a safe place and have them at hand for the next lessons.

App *Terminale*: scaricarla dal Microsoft Store ed impratichirsi

Claude Code

Important: If you already have Claude Code installed, then ensure to upgrade to the latest version:

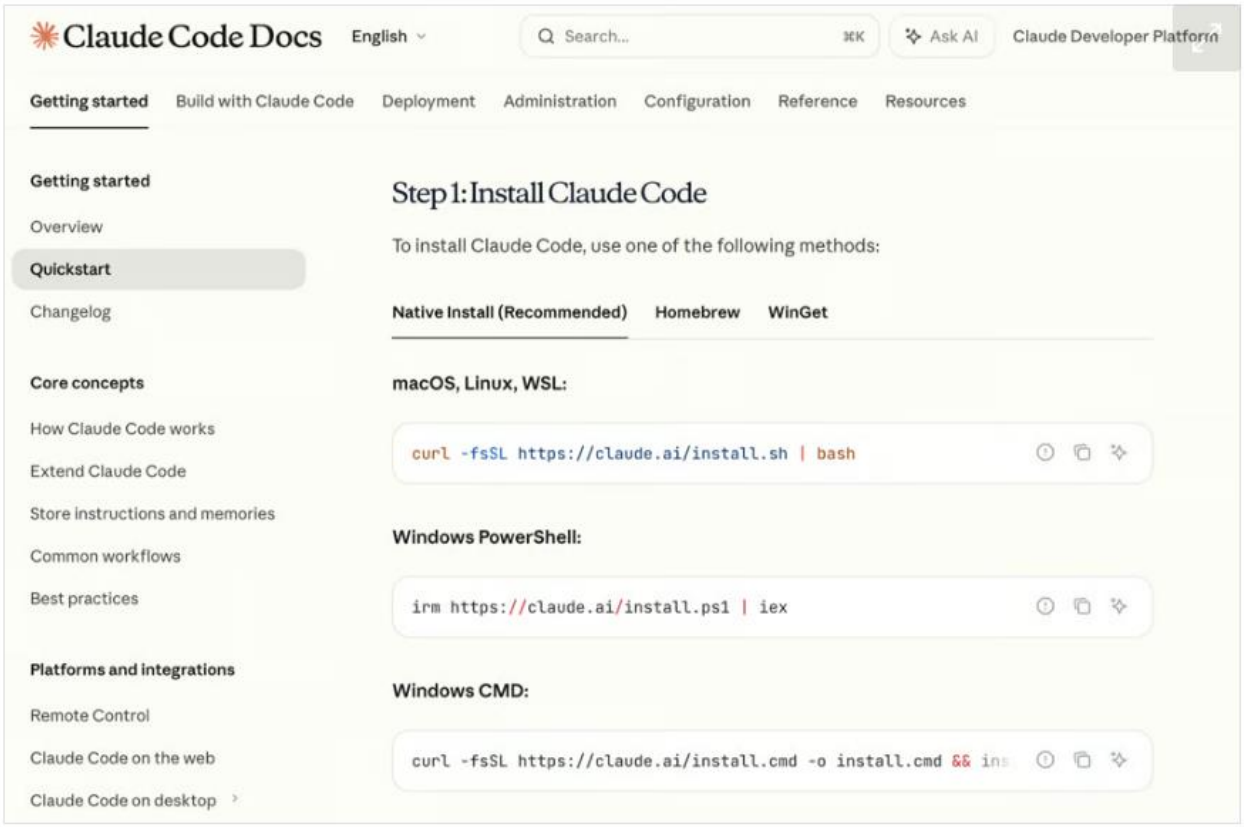

Shell

```
$ claude --upgrade
Current version: 2.1.77
Checking for updates to latest version...
Claude Code is up to date (2.1.77)
```

Alternatively, you can run `claude upgrade` without the two dashes (`--`) if the command above doesn't work for you. The Claude Code version on your system should be `2.1.76` or higher.

To install Claude Code on your system, open your **Terminal** and your **Browser** side-by-side. Visit the Claude Code quickstart guide in your browser and copy the **installation command** for your operating system:

In the Claude Code quickstart guide, you'll see a note saying *"Windows requires Git for Windows. Install it first if you don't have it."* In our experience, it's okay to Claude Code first, and install Git on your system in the next step.

Paste the installation command into your terminal and follow the steps on the screen. You can verify that the installation worked with this command:

Shell

```
$ claude --version
2.1.77 (Claude Code)
```

With this command you check the version of Claude Code. If your `claude` version is lower than the version you see above, please run `claude --upgrade` or `claude upgrade` before continuing to the next lesson.

Git

Note: Git and GitHub are often confused, but they're not the same thing:

- ***Git*** is version control software that runs on your computer. It tracks changes to your files and manages your project's history locally.
- ***GitHub*** is an online platform for hosting Git repositories. It provides collaboration tools that make sharing code, working with teams, and backing up your projects easier.

In this lesson, you'll take care of installing Git on your system.

Chances are that Git is already present on your system. To check whether Git is installed, run this command:

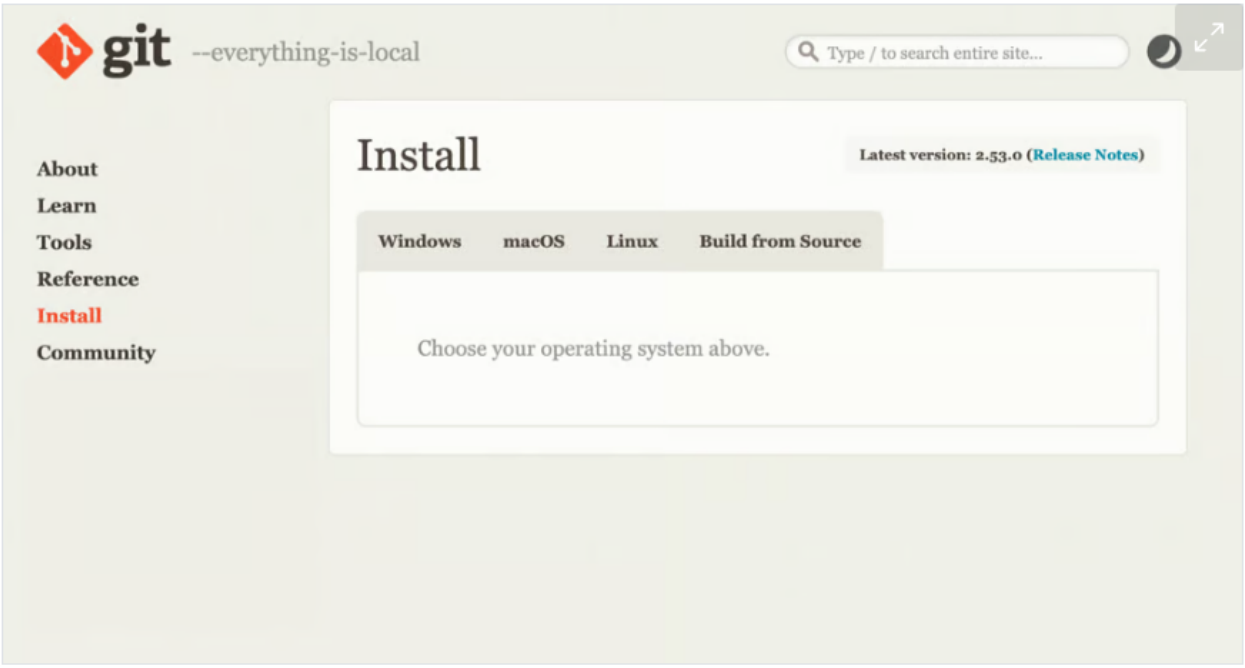

Shell

```
$ git --version
```

If this command displays a Git version, it's a good idea to refresh your knowledge about Git by reading How to Use Git: A Beginner's Guide and then continue with the next lesson.

Install Git on Your System

Luckily, Git provides installers for Windows, macOS, and Linux on its official website, offering a straightforward way to install Git on your machine. Because installation steps vary across operating systems, this guide links to the official documentation rather than reproducing those steps here:

If you prefer a graphical interface, you can install a Git client such as GitHub Desktop, Sourcetree, or GitKraken. These tools install Git automatically during setup.

Once installed, open your terminal and confirm that Git is available:

Shell

```
$ git --version
git version 2.50.1
```

Your Git version may appear slightly different from this example, depending on your operating system and when you installed Git. That's perfectly fine. As long as Git is installed and the command runs successfully, you'll be able to follow along without issues.

Uv

You're almost done with the setup! 💪

To comfortably manage Python versions and Python packages with Claude Code you use uv. uv integrates into one tool most of the functionality provided by tools like `pip`, `pip-tools`, `pipx`, `poetry`, `pyenv`, `twine`, `virtualenv`, and more. Therefore, uv is the perfect all-in-one solution for agentic coding.

In the official uv installation guide, you'll find several other installation options. For example, you can use tools like Homebrew and Cargo, depending on your current platform and operating system. However, in the steps below, you'll only explore the standalone installer.

Using the Standalone Installer

The uv project provides a standalone installer that you can use to download and install the tool in your system. Below are the relevant commands for the three main operating systems:

Windows PowerShell

```
PS> powershell -ExecutionPolicy ByPass -c "irm https://astral.sh/uv/install.ps1 | iex"
```

These commands will download and install the latest binary of uv in your system. Once you've downloaded and installed uv with the appropriate command, you can verify the installation by running the following command:

Shell

```
$ uv --version
uv 0.10.11
```

Now you're all set up with uv. In this case, you're using version `0.10.11`. It's okay if your specific version differs slightly.

To learn more about uv, check out this tutorial and its related video course:
